## GETTING TO KNOW

# GLIOBLASTOMA

**Most malignant** primary brain tumour in adults. (*WHO Grade IV*, IDH-wildtype).

**45.2%**  
Of all primary malignant CNS tumours.

**14-16 months**  
Median Survival post-diagnosis

**5.5%**  
5-year survival rate.

**~90%**  
of IDH-wildtype cases arise de novo in older patients

## MULTIMODAL CHARACTERIZATION OF GBM

### Radiological Image

- Edema Region
- Enhancing Tumor
- Necrotic Core

### Description

(A) T2 Weighted MRI Scan With Sub region Markings  
(B) Histopathological image of Glioblastoma ( Hematoxylin and Eosin stained )

## HISTOPATHOLOGICAL IMAGE (H&E STAIN)

- Pseudopalisading necrosis
- Microvascular proliferation
- Pleomorphic tumor cells
- Mitotic figures

# When Imaging isn't **ENOUGH**

# When Imaging isn't **ENOUGH**

## Foundations

**A medical scan shows structure,  
not always clear meaning.**

Medical images, specially Magnetic Resonance Imaging give us a detailed view of what's inside the body. We can see shapes, boundaries, and visible biological changes. But not every important detail is clearly obvious. Some differences are very subtle and obvious to overlook, especially in the early stages. So even though the information is there, understanding it completely is not always convenient !

# When Imaging isn't **ENOUGH**

# When Imaging isn't **ENOUGH**

### Foundations

## TP and PSP Often Indistinguishable on Conventional MRI

Both show contrast enhancement and lesion growth due to blood-brain barrier disruption, making them difficult to distinguish.

*DICOM Credit : University of Toronto (University Health Network, UHN)*

# When Imaging isn't **ENOUGH**

# When Imaging isn't **ENOUGH**

## Foundations

### Clinical Consequences of Misclassification

Clinically, this is important. In glioblastoma, different tumour regions can show similar post-treatment changes, making TP and PsP look alike. This can lead to misclassification, resulting in either unnecessary treatment changes or delayed intervention

### Glioblastoma

# When Imaging isn't **ENOUGH**

# When Imaging isn't **ENOUGH**

## Foundations

### A medical scan shows structure, not always clear meaning !

Conventionally used software from vendors like GE, Siemens, Philips, along with **conventional models**, remain limited in reliably distinguishing TP from PsP due to imaging regions overlap. Most approaches report performance  $\leq 75\%$  in accuracy. In this work, we adopt a fundamentally novel approach, achieving improved performance with an AUC of 0.89 and an F1-score of 0.90 [ Different Gradient Coils too ]

QUANTITATIVE PERFUSION IMAGING

# Graphical ABSTRACT

# Clinical Data ACQUISITION

All the patients were receipt of standard of care (SOC) therapy, including surgery followed by concurrent chemoradiotherapy (CCRT)

**Siemens Healthineers**, Erlangen(Germany), a classic 3T MAGNETOM Trio whole-body MR scanner with a 12 channel phased array head coil.

**MultiHance**, Bracco Imaging, Milano, Italy, a widely used **GCA ( Gadolinium Based Contrast Agents )** stain is used, at a dose of 0.07 mmol/kg.  
Delivered using a **power injector (Medrad, Indianola, PA, USA)**.

A total of **30** sequential measurements were acquired for each slice to assess contrast **wash in - washout** kinetics. [ Temporal resolution : **7** seconds per frame ]

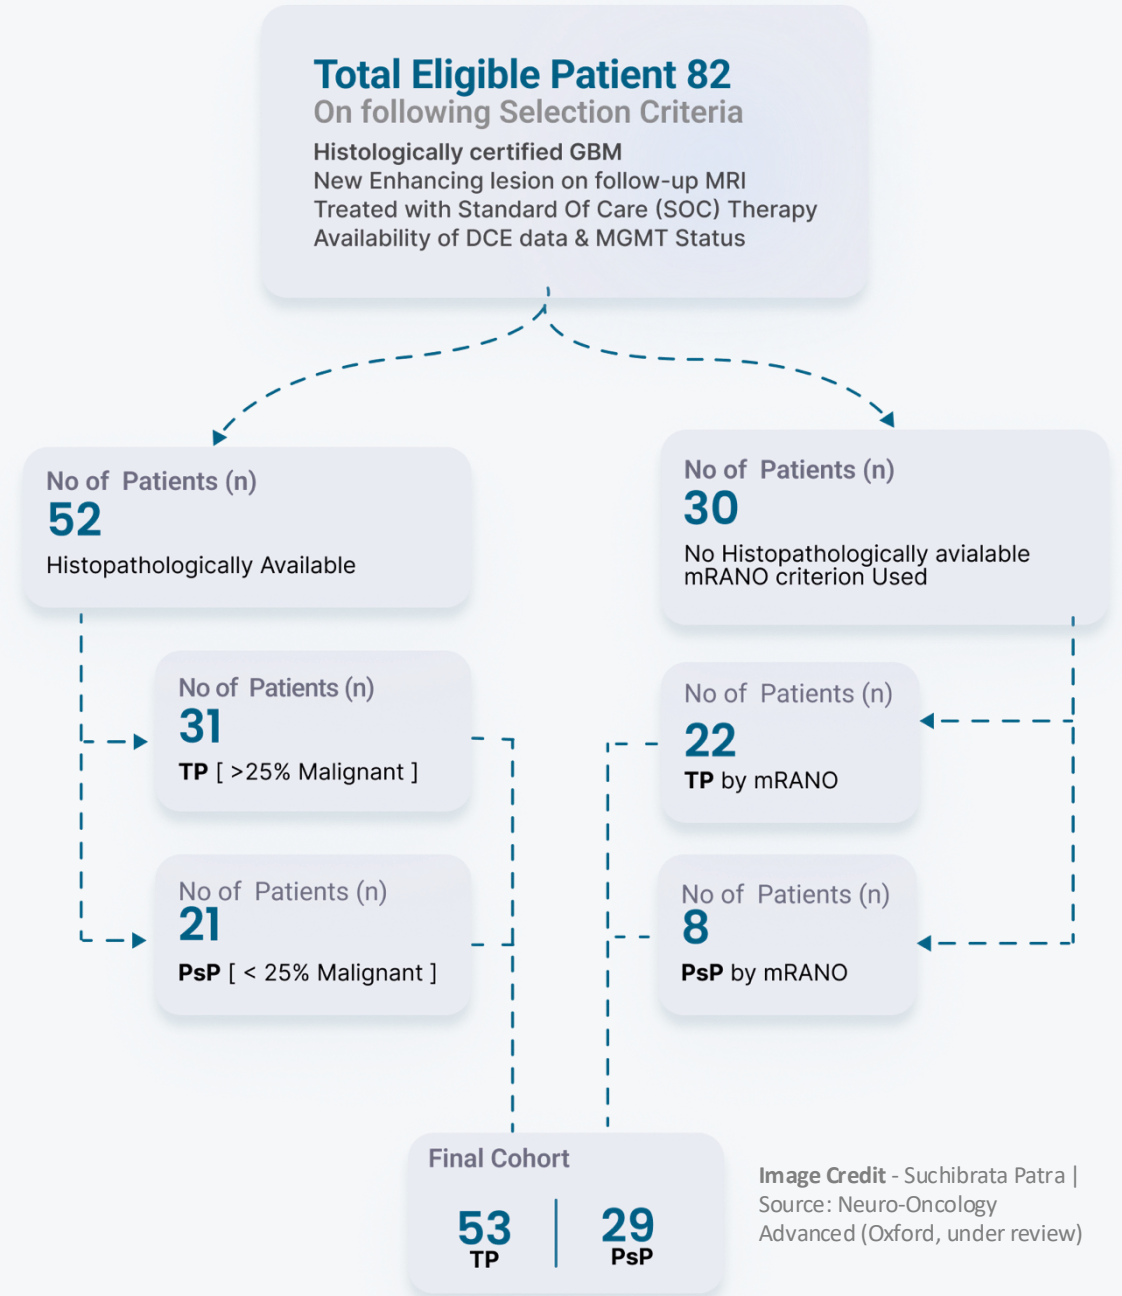

Figure A : Representative multiparametric MRI sequences (T1+C, FLAIR, DCE)

# Parameter Maps EXTRACTION

-  We began by generating **DCE-MRI parametric maps**, extracting key physiological parameters including  $K_{trans}$ ,  $V_e$ ,  $V_p$ ,  $K_{ep}$ ,  $\tau$
-  **In-house developed MATLAB toolbox** was used, incorporating multiple pharmacokinetic models such as Tofts, ETM, SSM, 2CXM, and 3S2X.
-  A subject-specific vascular input function (VIF) was then defined by placing an ROI over the superior sagittal sinus (SSS).
-  Following map generation, **post-contrast T1 and T2-FLAIR images** were co-registered and resliced to align with the DCE-MRI space. [ Rigid Body Affine Transformation was used ]
-  Tumours were segmented using nnU-Net [ **Gold standard** as a strong baseline, trained on BraTS dataset 2018-21] on co-registered PC-T1 and FLAIR images (Dice: 88.95%, BraTS), and volume was computed as voxel count  $\times$  voxel size.

## Figure

# Robust Feature SELECTION

## First Stage Selection

We performed feature selection using a two-stage reduction pipeline, motivated by the high dimensionality of radiomic features ( $n = 1073$ ) relative to sample size, where overfitting becomes inevitable without proper reduction.

In the first stage, the Non-Parametric Mann–Whitney U test was applied to evaluate the discriminatory power of each feature between TP and PsP. Features with  $p < 0.05$  were retained, reducing the feature space from 1073 to 86.

In the second stage, **Elastic Net regularization** ( With L1 (sparsity) and L2 (grouping) penalties ) was employed to further refine the feature set.

The hyperparameters ( $\alpha, \rho$ ) were optimized using grid search with five-fold stratified cross-validation, ensuring class balance across folds and robust generalization.

## Second Stage Selection

To address class imbalance ( $TP > PsP$ ), **ADASYN** was applied to the training set, which adaptively generates synthetic minority samples near decision boundaries, improving learning in difficult areas.  
**Kept the test set untouched to prevent data leakage.**

9:41 AM Tue 7 May Feature Selection Notes

### 1. FIRST STAGE - Mann-Whitney U Test

- Assessed each feature independently for discriminatory power between TP and PsP.
- For samples  $X = \{x_1, x_2, \dots, x_m\}$   
 $Y = \{y_1, y_2, \dots, y_n\}$

$$U = \sum_{i=1}^m \sum_{j=1}^n S(x_i, y_j) \quad \text{where} \quad S(x, y) = \begin{cases} 1 & x > y \\ \frac{1}{2} & x = y \\ 0 & x < y \end{cases}$$

Diagram: Stage 1 funnel showing 1073 features at the top and 86 features at the bottom, with a  $p < 0.05$  threshold indicated.

- Features with  $p < 0,05$  were retained.
- Radiomic distributions violate normality  $\rightarrow$  Non-parametric test more appropriate.
- Feature set reduced: **1,073  $\rightarrow$  86 features.**

---

### 2. SECOND STAGE - Elastic Net Regularization

- Applied Elastic Net regression to further refine the feature set.
- Combines L1 (sparsity) and L2 (grouping) penalties.

$$\hat{\beta} = \arg \min_{\beta} \left[ \frac{1}{2n} \|y - X\beta\|_2^2 + \alpha \left( \rho \|\beta\|_1 + \frac{1-\rho}{2} \|\beta\|_2^2 \right) \right]$$

where,  $\alpha \rightarrow$  overall regularization strength  
 $\rho \in [0,1] \rightarrow$  balances sparsity vs grouping

Diagram: Stage 2 funnel showing a refined feature set.

---

### 3. HYPERPARAMETER TUNING

- Hyperparameters ( $\alpha, \rho$ ) optimized using grid search with 5-fold stratified cross-validation.

\* All steps implemented in SciPy (v1.17.1) and scikit-learn (v1.8.0)

## Extended Tofts Model [ETM] + MGMT

No model achieved meaningful discrimination (TEAUC ≤ 0.68), with high training but poor validation performance indicating strong overfitting especially in **RF** and **XGB** and unstable specificity making the models clinically unreliable.

## T1 Post Contrast Model [ETM] + MGMT

**SVM** provides the best overall balance. **RF** attains the highest VAUC (0.83) but suffers from low specificity, and **LR** remains competitive indicating partial linear separability in the features.

## Parsimonious DCE Parameters

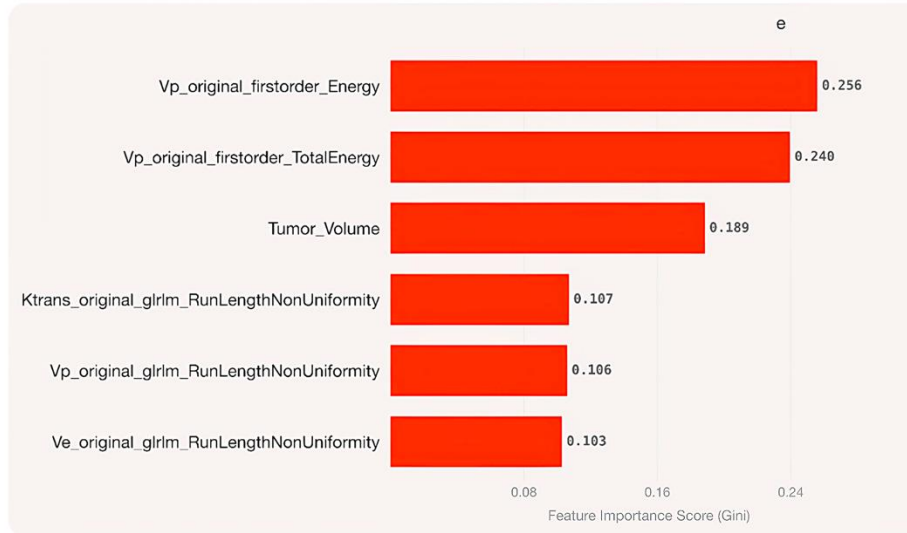

RF delivers the highest TEAUC (0.84 ± 0.09) and sensitivity (0.91 ± 0.13), showing improved feature quality, but its specificity is low and unstable, while SVM offers the best specificity (0.77 ± 0.12) with a slightly lower yet acceptable TEAUC.

## Parsimonious DCE + MGMT

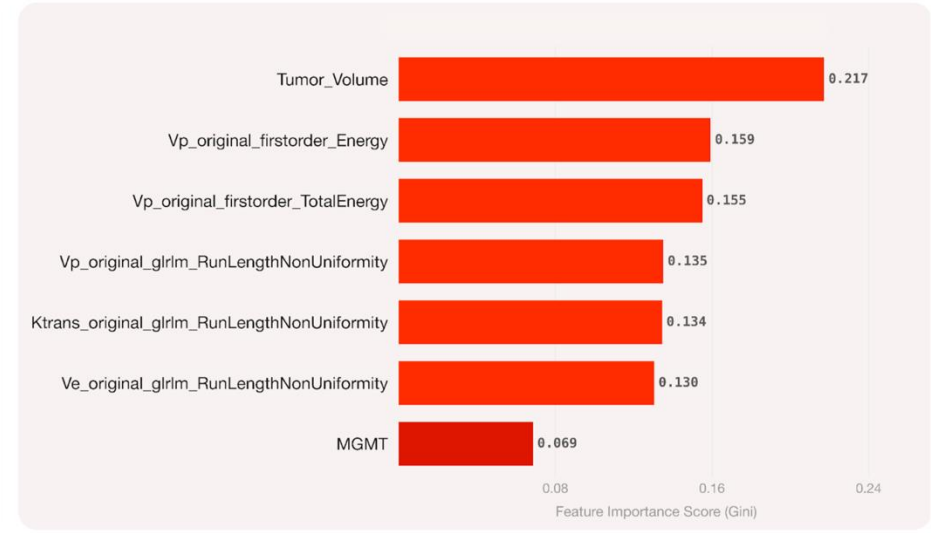

RF achieves the best overall performance (TEAUC 0.89, sensitivity 0.93, specificity 0.76, F1 0.90) and is the recommended deployment model, with clear gains over the MGMT-free setup highlighting the strong added value of molecular biomarker integration.

# Gini Feature IMPORTANCE

## Parsimonious Without MGMT Gini Importance

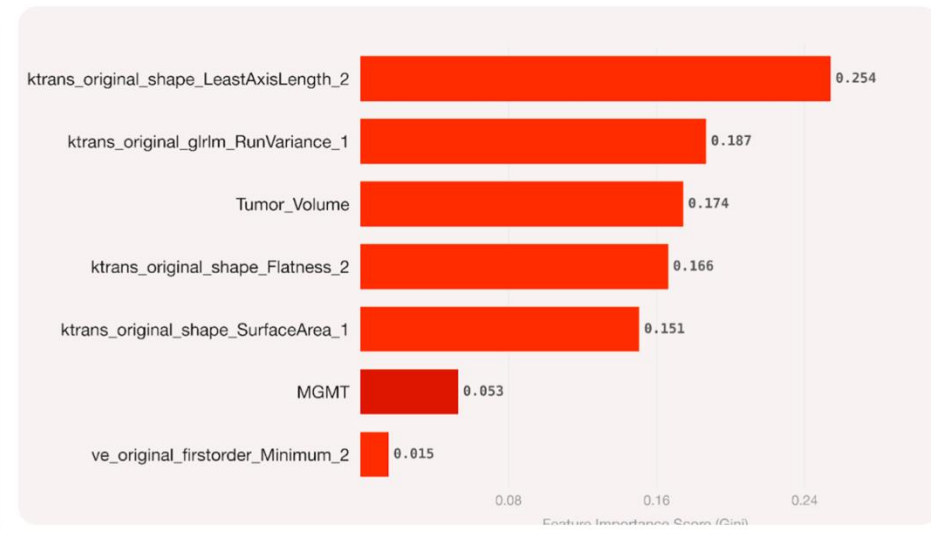

## Extended TOFTS with MGMT Gini Importance

## T1 Post Contrast with MGMT Gini Importance

## Parsimonious + MGMT Gini Importance

# DISCUSSION & CONCLUSION

## Discussion & Clinical Significance

**Parsimonious DCE + MGMT + RF** achieves SOTA performance (TEAUC 0.89, Sens 0.93, Spec 0.76), confirming optimal feature–model synergy

**Parsimonious PK** modelling + MGMT integration significantly enhance discriminative power over conventional approaches

Random Forest effectively captures complex, non-linear radiomic interactions, outperforming linear and boosting models

Enables high-confidence, non-invasive TP vs PsP differentiation, addressing a critical clinical uncertainty

## Study Limitations

Small, yet imbalanced cohort (**n=82**)

Single centre data, that's why scanner/protocol dependency may affect robustness

Mixed ground truth (histology + mRANO) → potential label inconsistency

No external validation has been performed. So, in reality the true generalisation still remains unproven

### Additional Constraints

Cross-sectional design - ignores longitudinal disease evolution.  
**MGMT** ambiguity (indeterminate cases) reduces interpretability

Limited clinical interpretability, because that requires SHAP.

### Extended TOFTS + MGMT

### T1 POST Contrast + MGMT

### Parsimonious Model

**Thank You**

# Backup Slides

Don't show them. In case of rendering issue paste these slides.

# $K^{trans}$

## Volume Transfer Constant

Rate at which contrast moves from plasma to the Extravascular Extracellular Space (EES)

Reflects Capillary Permeability & Surface Area

# $V_e$

## EES Volume Fraction

Fraction of tissue volume occupied by the Extravascular and Extracellular Space

Increased in edema/necrosis & lower in dense tumour

# $V_p$

## Plasma Volume Fraction

Fraction of tissue volume occupied by plasma (intravascular space).A

Reflects vascular Volume or Density

# $F_p$

## Plasma Flow Rate

Rate of plasma flowing through the capillary bed per unit tissue volume.

resents tissue Perfusion

# $\tau_i$

## Intracellular Water Lifetime

Average time water molecules spend inside cells.

Shorter  $\tau_i$  implies higher cell membrane

### Foundations

**A medical scan shows structure, not always clear meaning.**

Medical images, specially Magnetic Resonance Imaging give us a detailed view of what's inside the body. We can see shapes, boundaries, and visible biological changes. But not every important detail is clearly obvious. Some differences are very subtle and obvious to overlook, especially in the early stages. So even though the information is there, understanding it completely is not always convenient !

### Foundations

**TP and PSP Often Indistinguishable on Conventional MRI**

Both show contrast enhancement and lesion growth due to blood-brain barrier disruption, making them difficult to distinguish.

*DICOM Credit : University of Toronto (University Health Network, UHN)*

## Foundations

### Clinical Consequences of Misclassification

Clinically, this is important. In glioblastoma, different tumour regions can show similar post-treatment changes, making TP and PsP look alike. This can lead to misclassification, resulting in either unnecessary treatment changes or delayed intervention.

#### Glioblastoma

- Edema Region
- Enhancing Tumor
- Necrotic Core

#### Description

(A) T2 Weighted MRI Scans Without Sub region Markings  
(B) T2 Weighted MRI Scan With Sub region Markings

Image Credit : University of Pennsylvania Multi modal Brain Tumor Segmentation Challenge 2020

## Foundations

### A medical scan shows structure, not always clear meaning.

Despite advances, widely used software from vendors like GE, Siemens, Philips, along with **conventional models**, remain limited in reliably distinguishing TP from PsP due to imaging overlap. Most approaches report performance  $\leq 75\%$  in accuracy. In this work, we adopt a fundamentally novel approach, achieving improved performance with an AUC of 0.89 and an F1-score of 0.90 [ Different Gradient Coils too ]
